Whoop Experiments

Watch Demo (4 min) | Made by Luca Silveira

Turn Whoop's personalized health data into measurable behavior change through guided, AI-enabled experiments

Problem & Opportunity

WHOOP gives members detailed sleep and recovery data, while Journal offers dozens of behaviors to track. But members still need to figure out which habits are worth prioritizing, how much changing them might help, and whether tracking is worth the effort. The best starting point differs by member: someone logging late caffeine may need a different experiment than someone with inconsistent bedtimes.

My hypothesis: a personalized seven day experiment with a clear goal and results recap will motivate more members to start than an open-ended habit change.

Target Member
WHOOP members actively trying to improve their sleep or recovery who already use Journal or Coach but aren't sure which habits are worth changing first. Their familiarity with WHOOP's data makes them a practical starting audience. JTBD: Help identify one meaningful change in sleep & recovery, follow through consistently, and understand whether it's worth keeping.

MVP
Whoop Experiment is a new feature embedded within Whoop Coach and Journal that helps members test specific behavior changes through short, guided experiments.

- **Discover**: Members receive contextual experiment recommendations through Whoop Coach or nudges within Journal.
- **Select & Commit:** Choose from 3 initial experiments: Caffeine Cutoff, Bedtime consistency, or Earlier Last Meal with a personalized adjustable goal and 7 day duration. One experiment at a time.
- **Track:** Check ins are logged through journal, where they'll see progress
- **Learn:** Recap of goal adherence, sleep/recovery trends and comparison to baseline with recommended next steps (maintain habit, extend tracking or try another experiment).
- **Continue:** Members keep habit in Journal, save the results, and try another experiment.

AI's Role & Product Design Concepts

- **Recommend:** Use member goals, behavioral history, and health trends to prioritize and explain a relevant experiment.
- **Coach:** Identify adherence challenges and suggest adjustments based on the member's progress and routine.
- **Interpret:** Synthesize results into natural language and suggest next step
- **Reliability:** Deterministic logic handles adherence tracking, experiment progress, and metric calculations; AI handles personalization and interpretation.

Success Metrics:
- North Star: Experiment completion rate, positive ratings post-experiment check in, repeat
- Supporting: experiment exposure to start rate, daily logging coverage, 30 day adoption
- Business impact: Journal/Coach engagement, long-term retention compared to control
- Guardrails: Logging burden, abandonment, unhelpful conclusions, loss of trust
